The central notion in commutative algebra is that of a prime ideal. This provides a common generalization of the primes of arithmetic and the points of geometry.

M.F. Atiyah

Recall from last class that we discussed some consequences of unique factorization and some basic properties of commutative rings. Today we will show that that certain polynomial rings behave like the integers in that they have primes, congruences, and unique factorization. We will also discuss more general constructions and perhaps an algorithm or two.

The fields we know about so far are $\mathbb{Z}/p\mathbb{Z}$, \mathbb{Q} , \mathbb{R} , and \mathbb{C} . Let k be a field. What follows will be perhaps easiest if you set $k = \mathbb{Q}$ or \mathbb{R} in your mind. Then $k[x]$ denotes the ring of polynomials with coefficients coming from k . We can add and multiply polynomials as usual. It is left to you to check that the distributive law holds. The constant polynomials $z(x) = 0$ and $i(x) = 1$ are the additive identity and multiplicative identity of $k[x]$ respectively. Does $k[x]$ have units? Does it have zero divisors?

Definition 1. The degree of a polynomial $f \in k[x]$ is the positive integer which is the largest power of x appearing in f . We denote the degree of f by $\deg f$.

Proposition 1. $\deg fg = \deg f + \deg g$.

Proof. Let ax^n be the leading term of f and bx^m be the leading term of g . Thus $\deg f + \deg g = m + n$. The leading term of $fg = abx^{m+n}$ thus $\deg fg = m + n$. \square

We say that the degree of a constant polynomial is 0.

Proposition 2. The units of $k[x]$ are precisely the constant polynomials.

Proof. Let $p(x) = c = c1 + 0x + 0x^2 + 0x^3$ be a constant polynomial. Then since $c \in k$ which is a field, c has a multiplicative inverse d . Let $q(x) = d$ then $p(x)q(x) = cd = 1 = i(x)$. So $p(x)$ has a multiplicative inverse.

Suppose that $p(x)$ is a unit of $k[x]$. Then $p(x)$ has a multiplicative inverse $q(x)$ such that $p(x)q(x) = i(x) = 1$ for all x . Computing $\deg(p(x)q(x)) =$

$\deg p(x) + \deg q(x) = \deg i(x) = 0$. We must have that $\deg p(x) = \deg q(x) = 0$ since the degree is always positive. Thus $p(x)$ and $q(x)$ are both constant. \square

Proposition 3. When k is an integral domain, the polynomial ring $k[x]$ is an integral domain, that is, it has no zero divisors.

Proof. Since k is an integral domain, the nonzero constant polynomials are elements of k and therefore cannot be zero divisors. Let $f(x)$ be a polynomial of degree greater than 0. Suppose there is a nonzero polynomial $g(x)$ such that $f(x)g(x) = 0$. Then $\deg(f(x)g(x)) = 0$ but $0 < \deg f(x) \leq \deg(f(x)g(x))$ since $\deg(f(x)g(x)) = \deg f(x) + \deg g(x)$. \square

We turn now to section 2 of the modern text *A Classical Introduction to Modern Number Theory*.

Unique Factorization in $k[x]$

We will take k to be a field. Note that every field is an integral domain, that is, since all non-zero elements are units, there are no zero-divisors.

If $f, g \in k[x]$, we say that f divides g if there is an $h \in k[x]$ such that $fh = g$. A nonconstant polynomial p is said to be irreducible if $q|p$ implies that q is either a constant polynomial or a constant polynomial times p . Irreducible polynomials are the analog of prime numbers.

Lemma 1. Every nonconstant polynomial is the product of irreducible polynomials.

First look at the proof of Lemma 1 from lecture 2. We proved that by contradiction. Now we will use induction to give a direct proof of this lemma.

Proof. Polynomials of degree 1 are irreducible. Assume the result is true for polynomials of degree less than n and $\deg f = n$. If f is irreducible then we are done. Otherwise $f = gh$ where $1 \leq \deg g, \deg h < n$ by the induction assumption both g and h are products of irreducible polynomials. Thus, so is $f = gh$. \square

A monic polynomial is one whose leading term is 1. The polynomial $x^2 + x - 3$ is monic but $2x^5 + 1$ is not.

Let p be a monic irreducible polynomial. We define $\text{ord}_p(f)$ to be the integer a with the property that $p^a | f$ but $p^{a+1} \nmid f$. Note $\text{ord}_p(f) = 0$ if and only if $p \nmid f$.

Theorem 2. Let $f \in k[x]$. Then we can write

$$f = c \prod_p p^{a(p)},$$

where the product is over all monic irreducible polynomials and c is a constant. The constant c and all the exponents $a(p)$ are uniquely determined by f and $a(p) = \text{ord}_p(f)$.

Again, the existence of such a product follows from the previous lemma. The uniqueness of this product will require more work.

Now we will get a result which is analogous to article 3 and lemma 2 guaranteeing the existence of unique least residue for each modulus. This will allow us to extend the language of congruence to polynomials if we so desire. For the most part, our discussion of polynomials rings will take a modern approach.

Lemma 2. Let $f, g \in k[x]$. If $g \neq 0$, there exist polynomials $h, r \in k[x]$ such that $f = hg + r$ (classically, $f \equiv r \pmod{g}$), where either $r = 0$ or $r \neq 0$ and $\deg r \leq \deg g$.

Review the analogous proof in lecture 2.

Proof. If $g|f$ then set $h = f/g$ and $r = 0$. If $g \nmid f$, let $r = f - hg$ be the polynomial of least degree among all polynomials of the form $f - lg$ for $l \in k[x]$. We claim that $\deg r < \deg g$. If not let the leading term of r be ax^d and the leading term of g be bx^m where $m < d$. Thus, $ax^d/bx^m = \frac{a}{b}x^{d-m}$ is a polynomial in $k[x]$. Call it q . Note that the leading term of gq is $bx^m * \frac{a}{b}x^{d-m} = ax^d$, the leading term of r . We have

$$r = f - hg,$$

subtracting gq from both sides we obtain,

$$r - gq = f - (h + q)g.$$

Since gq and r have the same leading term, their difference is of degree less than r . Hence r cannot be the polynomial of least degree among all polynomials of the form $f - lg$, because we just showed $f - (h + q)g$ has lower degree than $f - hg$. We have reached a contradiction, therefore $\deg r < \deg g$ as desired. \square

Definition 1. If $f_1, f_2, \dots, f_n \in k[x]$, then (f_1, f_2, \dots, f_n) is the set of all polynomials of the form $f_1h_1 + f_2h_2 + \dots + f_nh_n$, where $h_1, h_2, \dots, h_n \in k[x]$. Collections of this form are called ideals. We say (f_1, f_2, \dots, f_n) is the ideal generated by the polynomials $f_1, f_2, \dots, f_n \in k[x]$.

Lemma 3. Given $f, g \in k[x]$ there is a $d \in k[x]$ such that $(f, g) = (d)$.

Proof. Let d be an element of least degree in (f, g) clearly $(d) \subset (f, g)$. We need to show the reverse inclusion. Let $c \in (f, g)$, then if $d \nmid c$ we have that there exists $q, r \in k[x]$ such that $c = dq + r$ where r has lower degree than d . Thus r has degree 0. So $d|c$ thus $c \in (d)$ and it follows that $(f, g) \subset (d)$ and thus $(f, g) = (d)$. \square

Definition 2. Let $f, g \in k[x]$. Then $d \in k[x]$ is said to be a greatest common divisor of f and g if d divides f and g , and if any other $c \in k[x]$ divides both f and g , then c must divide d .

Notice that if $d(x)$ is the greatest common divisor of two polynomials, then any constant multiple of $d(x)$ is also a greatest common divisor. When we talk about the greatest common divisor we mean the unique monic greatest common divisor.

Proposition 1. Given $f, g \in k[x]$ by lemma 3, there is a $d \in k[x]$ such that $(f, g) = (d)$. Furthermore, this d is the greatest common divisor of f and g .

Proof. Clearly, since $f, g \in (d)$ we have that $d|f$ and $d|g$. Now if h is any other polynomial dividing both f and g , $h|(lf + kg)$ for all polynomials l and k . Thus since $d \in (f, g)$ there exists some specific l and k such that $lf + kg = d$. Thus $h|d$. \square

Definition 3. Two polynomials, f and g are said to be relatively prime if the only common divisors of f and g are constants. Equivalently, if $(f, g) = (1)$. Note also that $(1) = k[x]$.

Proposition 2. If f and g are relatively prime and $f|gh$ then $f|h$.

Proof. Omitted. See the analogous proposition from notes 2. \square

Corollary 1. If p is an irreducible polynomial and $p|fg$ then $p|f$ or $p|g$.

Proof. Omitted. See the analogous proposition from notes 2. \square

Corollary 2. If p is a monic irreducible polynomial and $f, g \in k[x]$ we have

$$\text{ord}_p(fg) = \text{ord}_p(f) + \text{ord}_p(g).$$

Proof. Make the necessary changes to the proof of the related corollary from notes 2. \square

Exercise 1. Prove theorem 2.

Exercise 2. Complete all omitted proofs in these notes.
